

CsI Photon Detector Calibration using Kmu2

2015/12/15

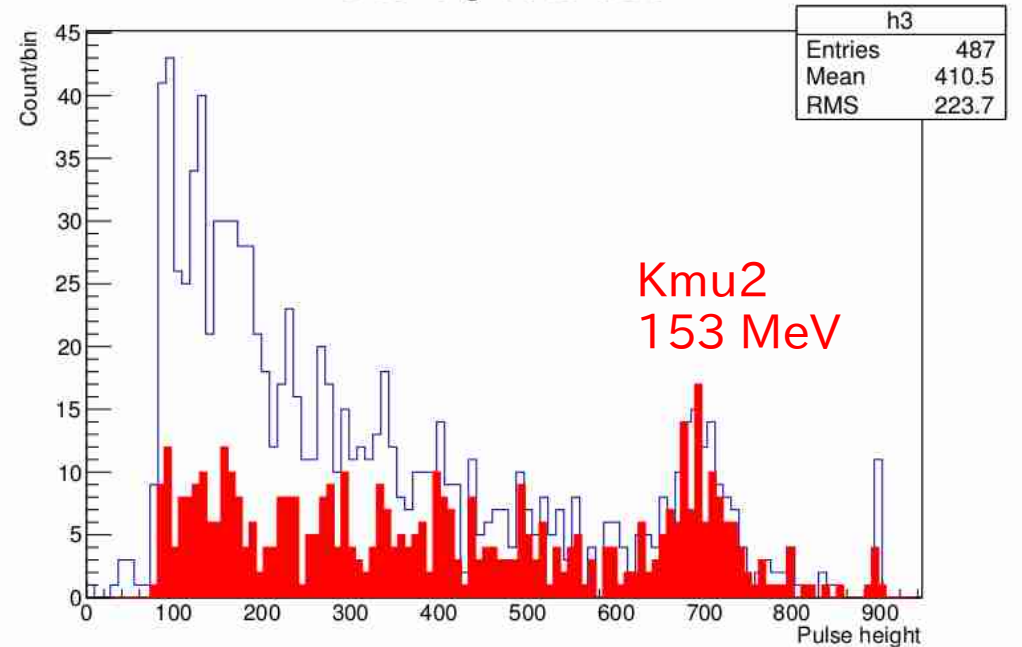

H. Ito

How to Calibration

Waveform

Pulse height distribution

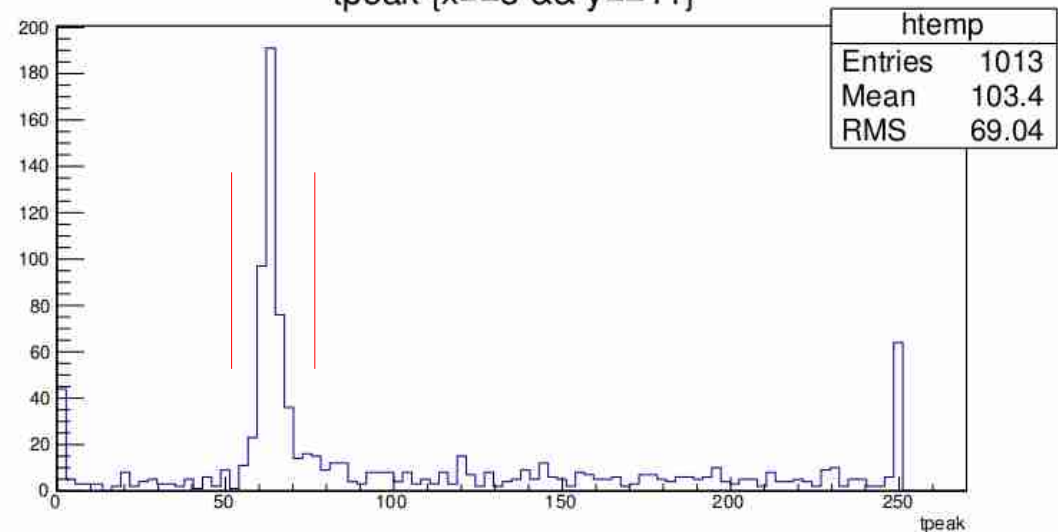

Selection of Event Tag

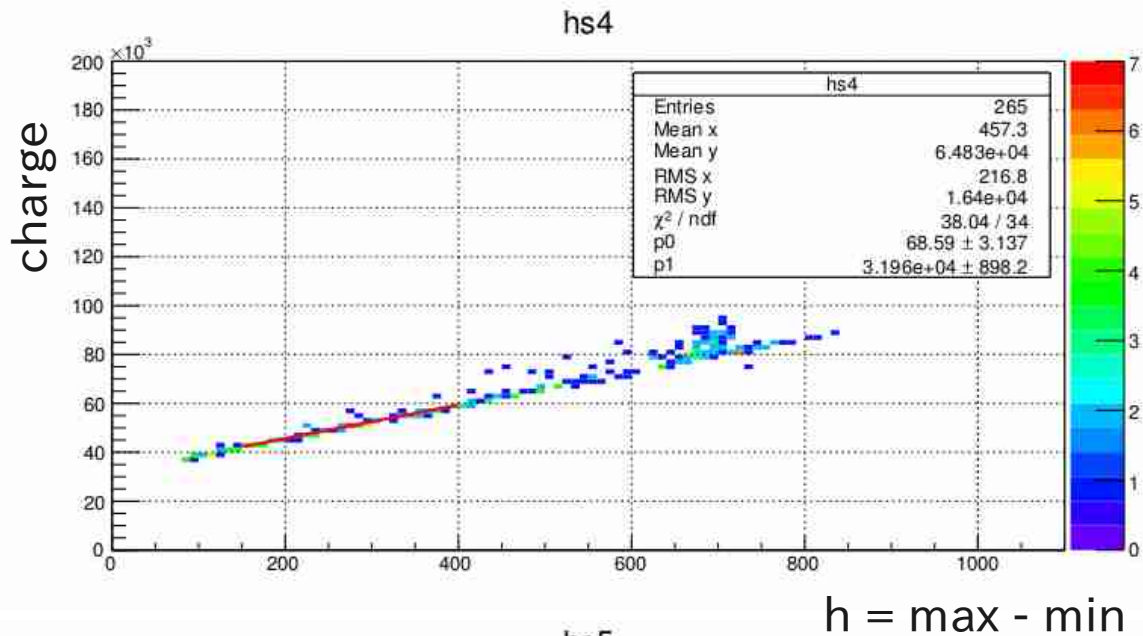

- K+ Stopped
- mu event (TOF, AC, PGC)
- Csl single HIT

Run #3059 – 3067
Total event: 47,352

tpeak {x==3 && y==11}

Extracted Kmu2

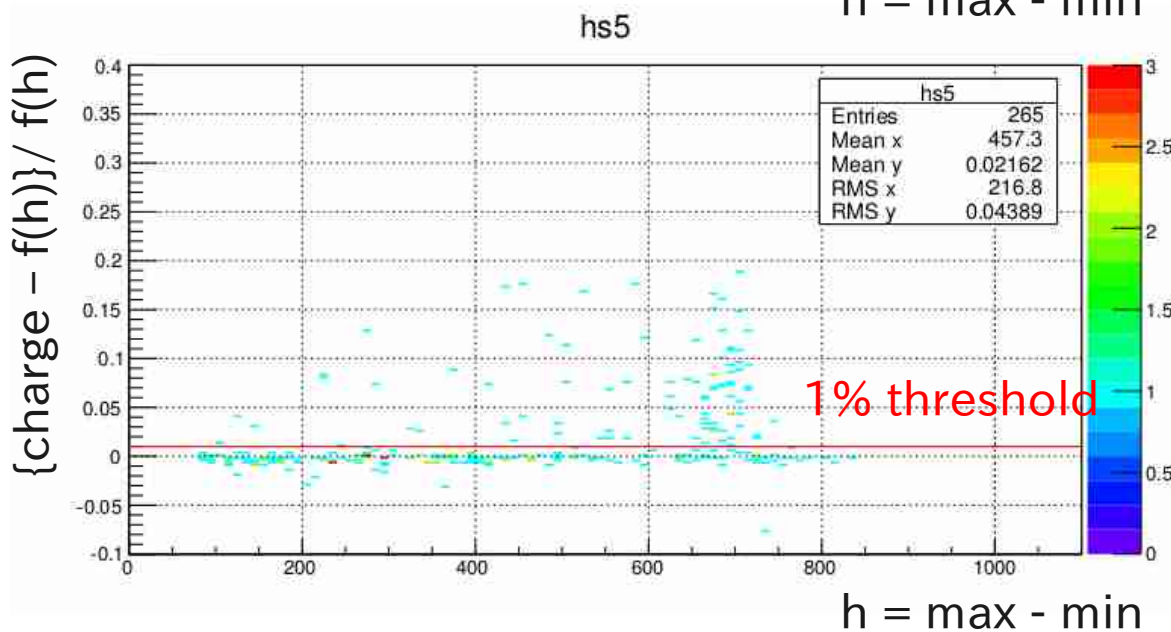

Charge vs. pulse height

Waveform is similar.
The wave has linearity.
But, a deviation is in 600-800.

Why?

e^+ from μ^+ make second pulse.
 μ tends to stop in Kmu2 region.

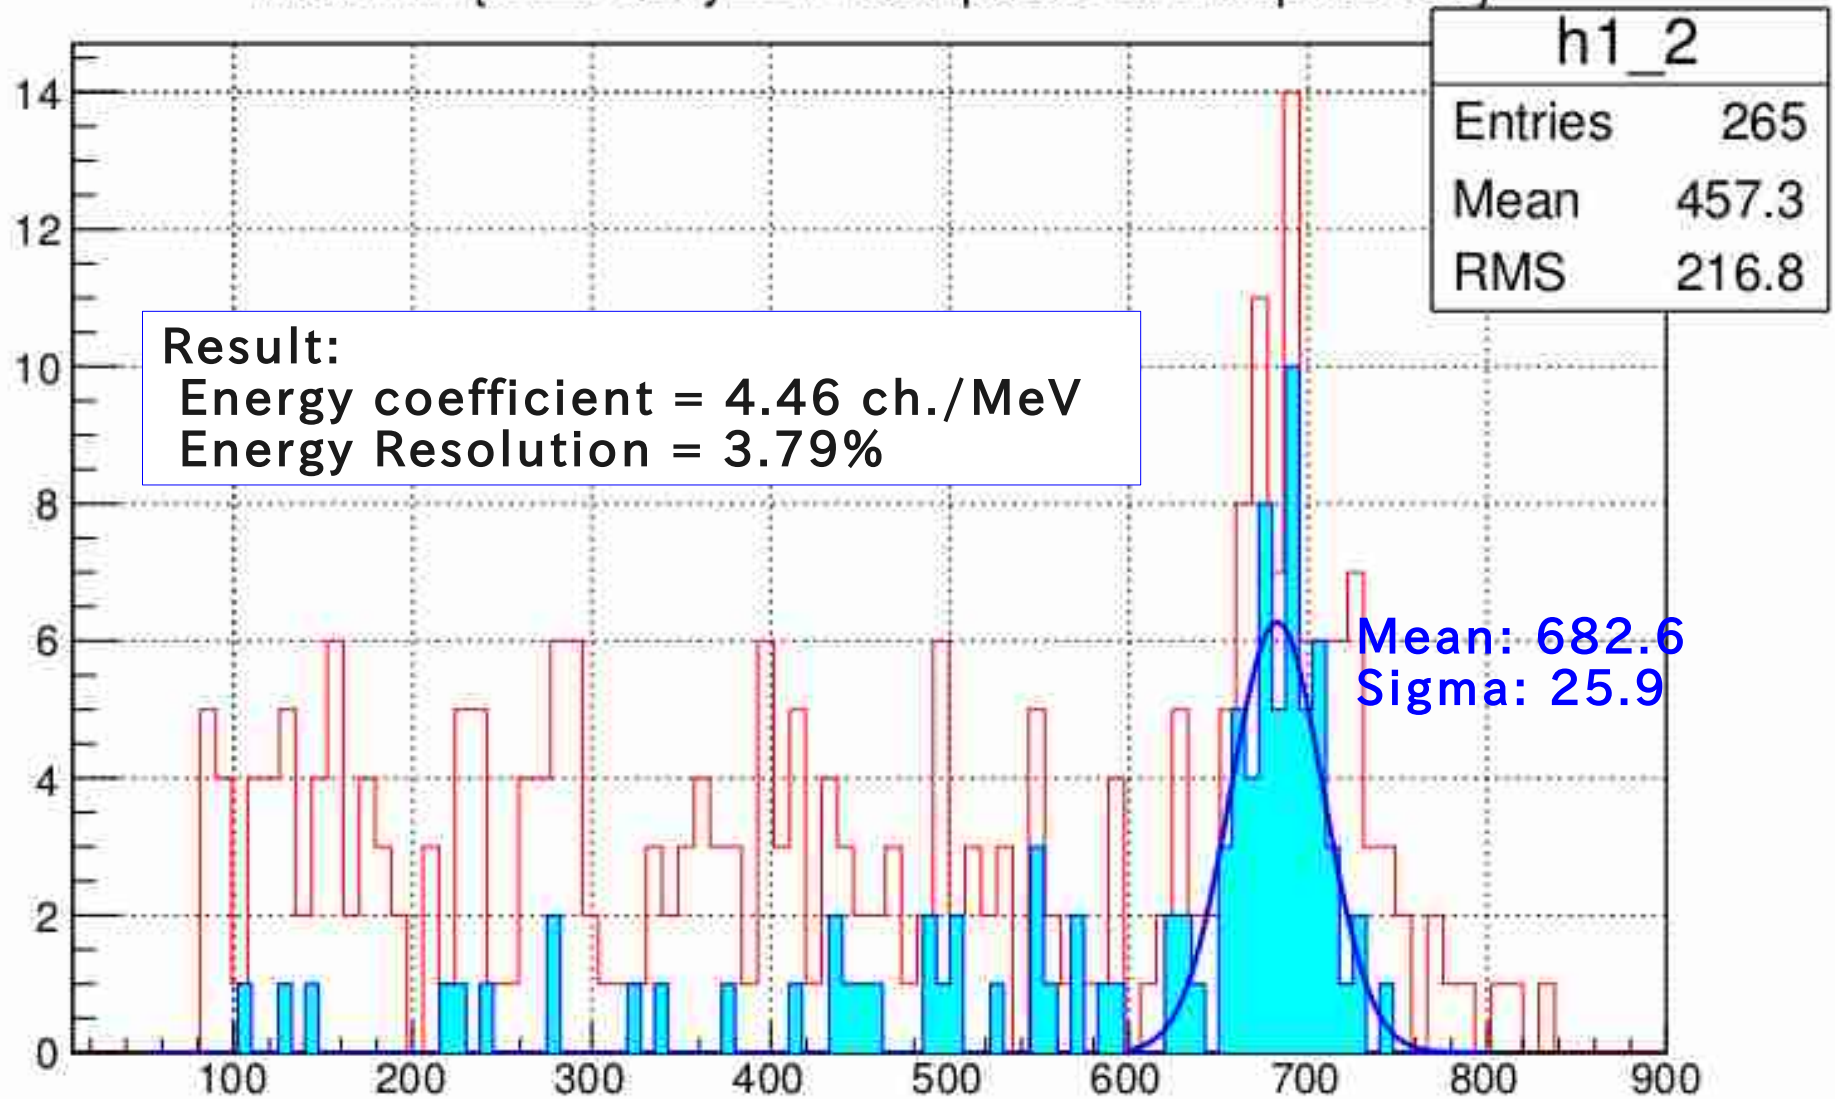

Fitting by the line

The function defined $f(h)$.
In the projection of the line,
selected over the threshold,
Kmu2 is only extracted.

Result

max-min {x==3 && y==11 && tpeak>60 && tpeak<65}

Future

Really?

The deviate is almost multiple wave.
Second pulse properties is confirmed.
Dose different of the time mean τ_{μ} ?
Is second height, max. 52 MeV?

Future Work

All crystal energy calibration
Confirmation the dt and h2
from all crystal.
Cosmic ray calibration
from e+ emitted stopped mu+
